

Annualized NPP rate through time

The Fortran module multiplies this rate by dt_years to obtain carbon input per timestep.

Carbon input from NPP per timestep

— Case 1 | target mean NPP = 3.50

Carbon pools through time

— Case 1 | target mean NPP = 3.50

Aggregate plant carbon through time

Structural demand and realized allocation

Allocation can be lower than demand because of limited storage or construction capacity.

Pool-specific structural demands

Realized structural increments

Turnover fluxes through time

— Case 1 | target mean NPP = 3.50

Carbon deficits and starvation-related diagnostics

Allometric residuals through time
Zero represents exact agreement with the corresponding target relationship.

Plant height through time

Final carbon pools by NPP scenario

Final aggregate carbon by NPP scenario
